Abstract

We investigate the sample path regularity of operator scaling \(\alpha\)-stable random fields. Such fields were introduced in [H. Biermék, M.M. Meerschaert, H.P. Scheffler, Operator scaling stable random fields, Stochastic Process. Appl. 117 (3) (2007) 312–332.] as anisotropic generalizations of self-similar fields and satisfy the scaling property \(\{X(c^E x); x \in \mathbb{R}^d\} \overset{f dd}{\sim} \{c^H X(x); x \in \mathbb{R}^d\}\) where \(E\) is a \(d \times d\) real matrix and \(H > 0\). In the case of harmonizable operator scaling random fields, the sample paths are locally Hölderian and their Hölder regularity is characterized by the eigen decomposition of \(\mathbb{R}^d\) with respect to \(E\).

In particular, the directional Hölder regularity may vary and is given by the eigenvalues of \(E\). In the case of moving average operator scaling \(\alpha\)-stable random fields, with \(\alpha \in (0, 2)\) and \(d \geq 2\), the sample paths are almost surely discontinuous.

Keywords: Operator scaling random fields; Stable and Gaussian laws; Hölder regularity; Hausdorff dimension

1. Introduction

In this paper we consider operator scaling stable random fields as introduced in [1]. More precisely, if \(E\) is a real \(d \times d\) matrix whose eigenvalues have positive real parts, a scalar-valued
random field \((X(x))_{x \in \mathbb{R}^d}\) is called \textit{operator scaling} for \(E\) and \(H > 0\) if

\[
\forall c > 0, \quad \{X(c^E x); x \in \mathbb{R}^d\} \overset{(f_{dd})}{=} \{c^H X(x); x \in \mathbb{R}^d\}, \tag{1}
\]

where \((f_{dd})\) means equality of finite dimensional distributions and as usual \(c^E = \exp(E \log c)\) with \(\exp(A) = \sum_{k=0}^{\infty} \frac{A^k}{k!}\) the matrix exponential. These fields can be seen as anisotropic generalizations of self-similar random fields. Let us recall that a scalar-valued random field \((X(x))_{x \in \mathbb{R}^d}\) is said to be \(H\)-\textit{self-similar} with \(H > 0\) if

\[
\forall c > 0, \quad \{X(cx); x \in \mathbb{R}^d\} \overset{(f_{dd})}{=} \{c^H X(x); x \in \mathbb{R}^d\}.
\]

Then a \(H\)-self-similar field is also an operator scaling field for the identity matrix \(E = I_d\) of size \(d \times d\). Numerous natural phenomena have been shown to be self-similar. For instance, self-similar random fields are required to model persistent phenomena in internet traffic, hydrology, geophysics or financial markets, e.g. [2–5]. A very important class of such fields are given by Gaussian random fields and especially by fractional Brownian fields. The fractional Brownian field \(B_H\), where \(H \in (0, 1)\) is the so-called Hurst parameter, is \(H\)-self-similar and has stationary increments, i.e. \(\{B_H(x + h) - B_H(h); x \in \mathbb{R}^d\} \overset{(f_{dd})}{=} \{B_H(x); x \in \mathbb{R}^d\}\) for any \(h \in \mathbb{R}^d\). It is an isotropic generalization of the famous fractional Brownian motion, implicitly introduced in [6] and defined in [7].

However, the isotropy property is a serious drawback for many applications in medicine [8,9], in geophysics [10] and in hydrology [11], just to mention a few. In particular, [8,9] introduce two classes of anisotropic Gaussian random fields for X-ray pictures of bones modeling, to help for diagnosis of osteoporosis. More precisely, [8] proposes to use the fractional Brownian sheet which exhibits different scaling properties in the \(d\) orthogonal directions that characterize its anisotropy. The fractional Brownian sheet, first introduced in [12], is operator scaling for a diagonal matrix but it does not have stationary increments, which is a natural assumption since bones can be considered as homogeneous materials. Therefore, [9] introduces anisotropic Brownian fields which have stationary increments. Proposition 5 of [9] shows that the directional regularity of any Gaussian random field with stationary increments is constant except maybe on a hyperplane of dimension at most \(d - 1\). However, the sample path regularity of the Brownian fields studied in [9] does not depend on any direction. The Gaussian random fields introduced in [1] illustrate Proposition 5 of [9]. These random fields were introduced to model sedimentary aquifers, which exhibit different scaling properties in different directions and not necessarily orthogonal ones (see [11]). They have stationary increments, satisfy the operator scaling property (1) and their anisotropic behavior is driven by a \(d \times d\) matrix \(E\), not necessarily diagonal. Moreover, both Gaussian and \(\alpha\)-stable operator scaling random fields are defined in [1]. Actually, Gaussian random fields are not convenient for some heavy tails phenomena modeling. For this purpose, \(\alpha\)-stable random fields have been introduced. Let us recall that a scalar-valued random field \(\{X(x); x \in \mathbb{R}^d\}\) is symmetric \(\alpha\)-stable (SoS), for \(\alpha \in (0, 2]\), if any linear combination \(\sum_{k=1}^{n} a_k X(x_k)\) is SoS. We address to [4] for a well understanding of such fields. Self-similar isotropic \(\alpha\)-stable fields with stationary increments have been extensively used to propose alternative to Gaussian modeling (see [13,5] for instance). Then, operator scaling stable random fields, as defined by [1], are well fitted to mimic persistent, heavy-tailed and anisotropic phenomena.

Two different classes of such fields are defined in [1], using a moving average representation as well as an harmonizable one. In the Gaussian case \(\alpha = 2\), according to [1] there exist
modifications of these fields which are almost surely Hölder-continuous of certain indices. We give similar results here in the stable case \( \alpha \in (0, 2) \) for harmonizable operator scaling stable random fields. Actually, we obtain their critical global and directional Hölder exponents, which are given by the eigenvalues of \( E \). In general, such fields are anisotropic and their sample path properties varies with the direction. In particular, in the case where \( E \) is diagonalizable, for any eigenvector \( \theta_j \) associated with the real eigenvalue \( \lambda_j \), harmonizable operator scaling stable random fields admit \( H_j = 1/\lambda_j \) as critical Hölder exponent in direction \( \theta_j \). Let us point out that we establish an accurate upper bound for the modulus of continuity. Such upper bound has already been given in the case of real harmonizable fractional stable motions \((d = 1)\) in [14] and in the case of some Gaussian random processes in [15]. Then, in this paper, we generalize these results to any dimension \( d \) and any harmonizable operator scaling stable fields. We also obtain such an upper bound in the case of Gaussian operator scaling random fields, which improves the sample path properties established in [1].

Furthermore, whereas in the Gaussian case \( \alpha = 2 \), moving average and harmonizable fields have the same kind of sample path regularity properties, this is no more true in the case \( \alpha \in (0, 2) \). In particular, we show that for \( d \geq 2 \), a moving average operator scaling stable random field does not admit any continuous modification. Remark that if \( d = 1 \), the sample path regularity properties are already known since the processes studied are self-similar moving average stable processes, see for example [4,14,16].

One of the main tools for the study of sample paths of operator scaling random fields is the change of polar coordinates with respect to the matrix \( E \) introduced in [17]. If \( X \) is a Gaussian operator scaling random field with stationary increments, using (1), we can write its variogram as

\[
v^2(x) = \mathbb{E}
\left( X^2(x) \right) = \tau_E(x)^{2H} \mathbb{E} \left( X^2(\ell_E(x)) \right),
\]

where \( \tau_E(x) \) is the radial part of \( x \) with respect to \( E \) and \( \ell_E(x) \) is its polar part. Therefore, in the Gaussian case, the sample path regularity depends on the behavior of the polar coordinates \((\tau_E(x), \ell_E(x))\) around \( x = 0 \). Such property also holds in the stable case \( \alpha \in (0, 2) \). The Hölder sample path regularity properties follow from estimates of \( \tau_E(x) \) compared to \( \|x\| \). These estimates are given in Section 3 and their proofs are postponed to the Appendix.

Furthermore, the other main tool we use to study the sample paths of harmonizable operator scaling \( \alpha \)-stable random fields is a series representation. Representations in series of infinitely divisible laws have been studied in [18–21]. As in [14], our study is based on a LePage series representation. Actually, the main idea is to choose a representation which is a conditionally Gaussian series.

In Section 2, we recall the definition of harmonizable operator scaling random fields. Then, Sections 3 and 4 are devoted to the main tools we need for the study of their sample path regularity. More precisely, Section 3 deals with the polar coordinates with respect to a matrix \( E \) and Section 4 gives the LePage series representation. In Section 5, the sample path properties of harmonizable operator scaling random fields and the Hausdorff dimension of their graph are given. Section 6 is concerned with moving average operator scaling random fields.

2. Harmonizable representation

Let us recall the definition of harmonizable operator scaling stable random fields, introduced by [1]. Let us stress that the parametrization used in this paper is not the same one as in [1], see Remark 2.1.
Let $E$ be a real $d \times d$ matrix. Let $\lambda_1, \ldots, \lambda_d$ be the complex eigenvalues of $E$ and $a_j = \Re \left( \lambda_j \right)$ for each $j = 1, \ldots, d$. We assume that
\[
\min_{1 \leq j \leq d} a_j > 1. \tag{2}
\]

Let $\psi : \mathbb{R}^d \rightarrow [0, \infty)$ be a continuous, $E'$-homogeneous function, which means according to Definition 2.6 of [1] that
\[
\psi(cE'x) = c\psi(x) \quad \text{for all } c > 0 \text{ and } x \in \mathbb{R}^d.
\]
Moreover, we assume that $\psi(x) \neq 0$ for $x \neq 0$. Such functions were studied in detail in [17]. Chapter 5 and various examples are given in Theorem 2.11 and Corollary 2.12 of [1].

Let $0 < \alpha \leq 2$ and $W_\alpha (d\xi)$ be a complex isotropic $\alpha$-stable random measure on $\mathbb{R}^d$ with Lebesgue control measure (see [4] p.281). If $\alpha = 2$, $W_\alpha (d\xi)$ is a complex isotropic Gaussian random measure. Let $q = \text{trace} (E)$.

**Definition 2.1.** The random field
\[
X_\alpha (x) = \Re \int_{\mathbb{R}^d} \left( e^{i(x, \xi)} - 1 \right) \psi(\xi)^{-1 - q/\alpha} W_\alpha (d\xi), \quad x \in \mathbb{R}^d, \tag{3}
\]
is called harmonizable operator scaling stable random field.

**Remark 2.1.** As already mentioned, (3) is not exactly the representation used in [1] to define an harmonizable operator scaling stable random field. However, the class of random fields defined by (3) and the class of harmonizable operator scaling stable random fields defined in [1] are the same. More precisely, let $\tilde{E}$ be a real $d \times d$ matrix, $\tilde{q} = \text{tr} \tilde{E}$ and $\tilde{\psi} : \mathbb{R}^d \rightarrow [0, +\infty[ \text{ a } \tilde{E}'$-homogeneous function. For some convenient $H > 0$, let us consider
\[
X_{\tilde{\psi}} (x) = \Re \int_{\mathbb{R}^d} \left( e^{i(x, \xi)} - 1 \right) \tilde{\psi}(\xi)^{-1 - H - q/\alpha} W_\alpha (d\xi), \quad x \in \mathbb{R}^d, \tag{4}
\]
an harmonizable operator scaling stable random field as defined in [1]. Let $\psi = \tilde{\psi}^H$ and $E = \tilde{E} / H$. Then, $\psi$ is a $E'$-homogeneous function and
\[
X_{\tilde{\psi}} (x) = \Re \int_{\mathbb{R}^d} \left( e^{i(x, \xi)} - 1 \right) \psi(\xi)^{-1 - q/\alpha} W_\alpha (d\xi) = X_\alpha (x)
\]
with $X_\alpha$ defined by (3). Furthermore, $\tilde{\psi}, \tilde{E}$ and $H$ satisfy the assumptions of Theorem 4.1 of [1] if and only if $\psi$ and $E$ satisfy our assumptions.

**Remark 2.2.** For notational sake of simplicity we denote the kernel function by
\[
f (x, \xi) = \left( e^{i(x, \xi)} - 1 \right) \psi(\xi)^{-1 - q/\alpha}, \quad \xi \in \mathbb{R}^d \setminus \{0\}. \tag{5}
\]
Let us remark that, since (2) is fulfilled, $f (x, \cdot) \in L^\alpha (\mathbb{R}^d)$ for any $x \in \mathbb{R}^d$, which is a necessary and sufficient condition for $X_\alpha$ to be well-defined by (3). Moreover, from Corollary 4.2 of [1], $X_\alpha$ has stationary increments and satisfies the following operator scaling property
\[
\forall \varepsilon > 0, \quad \left\{ X_\alpha (\varepsilon^E x); x \in \mathbb{R}^d \right\} \overset{(f \text{ i.i.d})}{=} \varepsilon X_\alpha (x); x \in \mathbb{R}^d \right\}. \tag{6}
\]
Note that, for any $H > 0$, since $X_\alpha = X_{\tilde{\psi}^H}$ is also defined by (4),
Assume that $22$ is a real number. Then we can define $\|x\|_H$ with $\|\cdot\|$ the Euclidean norm. Then the random field $X_\alpha$ defined by $3$ is a real harmonizable stable random field (see Chapter 6 of [17]) for $E = I_d/H$ and [7] for $E = I_d$, which means that

$$\forall c > 0, \quad \{X_\alpha(cx); x \in \mathbb{R}^d\} \overset{(f dd)}{=} \{c^H X_\alpha(x); x \in \mathbb{R}^d\},$$

with $E = HE$, according to Corollary 4.2 of [1]. Actually, (7) is simply obtained from (6) by choosing $c = \varepsilon^{1/H}$. This is related Remark 4.4 of [1].

Now, let us give some examples of operator scaling harmonizable stable random fields.

**Example 2.1.** Let $I_d$ be the identity matrix of size $d \times d$, $H \in (0,1)$, $E = I_d/H$ and $\psi(x) = \|x\|_H$ with $\|\cdot\|$ the Euclidean norm. Then the random field $X_\alpha$ defined by $3$ is a real harmonizable stable random field (see [4] for details on such fields). In this case, $X_\alpha$ satisfies (6) for $E = I_d/H$ and (7) for $E = I_d$, which means that

$$\forall c > 0, \quad \{X_\alpha(cx); x \in \mathbb{R}^d\} \overset{(f dd)}{=} \{c^H X_\alpha(x); x \in \mathbb{R}^d\},$$

i.e. $X_\alpha$ is self-similar with exponent $H$. Let us quote that, if $\alpha = 2$, $X_\alpha$ is a fractional Brownian field and its critical Hölder exponent is given by its Hurst index $H$ (see Theorem 8.3.2 of [22] for instance).

**Example 2.2.** Assume that $E$ is diagonalizable and that all its eigenvalues are real, denoted by $(a_j)_{1 \leq j \leq d}$. Let $(\theta_j)_{1 \leq j \leq d}$ be a basis of some corresponding eigenvectors and consider the function $\psi$ defined by

$$\psi(x) = \left(\sum_{j=1}^d |\langle x, \theta_j \rangle|^{2/a_j}\right)^{1/2}, \quad x \in \mathbb{R}^d.$$ 

The function $\psi$ is clearly continuous and non-negative on $\mathbb{R}^d$. Moreover, since

$$\langle c^{E^t}x, \theta_j \rangle = \langle x, c^E\theta_j \rangle = c^{a_j}\langle x, \theta_j \rangle,$$

$\psi$ is also $E^t$-homogeneous. Finally, $\psi(x) = 0$ if and only if $x = 0$, since $(\theta_j)_{1 \leq j \leq d}$ is a basis of $\mathbb{R}^d$. Then we can define $X_\alpha$ by (3). For all $j = 1, \ldots, d$, the operator scaling property (6), applied with $\varepsilon = \varepsilon^{1/a_j}$, implies that

$$\forall c > 0, \quad \{X_\alpha(c t \theta_j); t \in \mathbb{R}\} \overset{(f dd)}{=} \{c^{1/a_j} X_\alpha(t \theta_j); t \in \mathbb{R}\},$$

since $(c^{1/a_j})^E \theta_j = (c^{1/a_j})^{a_j} \theta_j = c \theta_j$. Therefore, the random field $X_\alpha$ is self-similar with exponent $H_j = 1/a_j$ in the direction $\theta_j$. In particular, in the Gaussian case ($\alpha = 2$), the process $(X_2(t \theta_j))_{t \in \mathbb{R}}$ is a fractional Brownian motion with Hurst index $H_j$ and its critical Hölder exponent is equal to $H_j$.

One of the main tool in the study of operator scaling random fields is the change of coordinates in a kind of polar coordinates with respect to the matrix $E$. Then, before we study the sample path regularity of $X_\alpha$, we recall in the next section the definition of these coordinates and give some estimates of the radial part.

### 3. Polar coordinates

According to Chapter 6 of [17], since $E$ is a real $d \times d$ matrix whose eigenvalues have positive real parts, there exists a norm $\|\cdot\|_E$ on $\mathbb{R}^d$ such that the map

$$\Psi_E : \quad (0, \infty) \times S_E \longrightarrow \mathbb{R}^d \setminus \{0\} \quad (r, \theta) \longmapsto r^E \theta$$
is a homeomorphism, where
\[ S_E = \{ x \in \mathbb{R}^d : \|x\|_E = 1 \} \] (8)
is the unit sphere for \( \| \cdot \|_E \). Hence we can write any \( x \in \mathbb{R}^d \setminus \{0\} \) uniquely as
\[ x = \tau_E(x)E \ell_E(x) \] (9)
with \( \tau_E(x) > 0 \) and \( \ell_E(x) \in S_E \). Here, for any \( x \in \mathbb{R}^d \setminus \{0\} \), \( \tau_E(x) \) should be interpreted as the radial part of \( x \) and \( \ell_E(x) \in S_E \) as its directional part. Moreover, \( x \mapsto \tau_E(x) \) and \( x \mapsto \ell_E(x) \) are continuous maps. We also know that \( \tau_E(x) \to \infty \) as \( x \to \infty \) and \( \tau_E(x) \to 0 \) as \( x \to 0 \). Hence we can extend \( \tau_E \) continuously by setting \( \tau_E(0) = 0 \). Finally, we can observe that \( S_E = \{ x \in \mathbb{R}^d : \tau_E(x) = 1 \} \) is a compact set and define
\[ m_E = \min_{S_E} \|x\| \quad \text{and} \quad M_E = \max_{S_E} \|x\|. \] (10)

Let us now recall the formula of integration in polar coordinates established in [1].

**Proposition 3.1.** There exists a unique finite Radon measure \( \sigma_E \) on the unit sphere \( S_E \) defined by (8) such that for all \( f \in L^1(\mathbb{R}^d, dx) \),
\[ \int_{\mathbb{R}^d} f(x) \, dx = \int_0^{\infty} \int_{S_E} f(r^E \theta) \sigma_E(d\theta) r^{d-1} \, dr. \]

As already mentioned in the introduction, the Hölder sample path regularity properties of \( X_\alpha \) follow from estimates of \( \tau_E(x) \) compared to \( \|x\| \) around \( x = 0 \), i.e. from the Hölder regularity of \( \tau_E \) around 0, see [1]. Then, in order to get an upper bound for the modulus of continuity (for any \( \alpha \)), we need some precise estimates of \( \tau_E(x) \).

As done in [23] for the study of operator-self-similar Gaussian random fields we use the Jordan decomposition of the matrix \( E \) to get estimates of \( \tau_E \). From the Jordan decomposition’s theorem (see [24] p. 129 for instance), there exists a real invertible \( d \times d \) matrix \( P \) such that \( D = P^{-1} E P \) is of the real canonical form, which means that \( D \) is composed of diagonal blocks which are either Jordan cell matrix of the form
\[
\begin{pmatrix}
\lambda & 0 & \cdots & 0 \\
1 & \lambda & \cdots & \vdots \\
\vdots & \ddots & \ddots & 0 \\
0 & \cdots & 1 & \lambda
\end{pmatrix}
\]
with \( \lambda \) a real eigenvalue of \( E \) or blocks of the form
\[
\begin{pmatrix}
A & 0 & \cdots & 0 \\
I_2 & A & \ddots & \vdots \\
\vdots & \ddots & \ddots & 0 \\
0 & \cdots & 0 & I_2
\end{pmatrix}
\]
with \( A = \begin{pmatrix} a & -b \\ b & a \end{pmatrix} \) and \( I_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \),
(11)

where the complex numbers \( a \pm ib \ (b \neq 0) \) are complex conjugated eigenvalues of \( E \).
Let us denote by $\| \cdot \|$ the subordinated norm of the Euclidean norm on the matrix space. Precise estimates of $\tau_E$ follow from the next lemma.

**Lemma 3.2.** Let $J$ be either a Jordan cell matrix of size $l$ or a block of the form (11) of size $2l$ associated with the eigenvalue $\lambda \in \mathbb{C}$. Then, for any $t \in (0, e^{-1}) \cup \{e, +\infty\}$

$$
t^a \leq \|t^J\| \leq \sqrt{2}let^a \left|\log t\right|^{l-1}
$$

with $a = \Re(\lambda)$.

**Proof.** See the Appendix. □

Let us be more precise on the Jordan decomposition of $E$.

**Notation.** Let us recall that the eigenvalues of $E$ are denoted by $\lambda_j, j = 1, \ldots, d$ and that $a_j = \Re(\lambda_j) > 1$ for $j = 1, \ldots, d$. There exist $J_1, \ldots, J_p$, where each $J_j$ is either a Jordan cell matrix or a block of the form (11), and $P$ a real $d \times d$ invertible matrix such that

$$
E = P \begin{pmatrix}
J_1 & 0 & \ldots & 0 \\
0 & J_2 & 0 & \vdots \\
\vdots & \ddots & \ddots & 0 \\
0 & \ldots & 0 & J_p
\end{pmatrix} P^{-1}.
$$

We can assume that each $J_j$ is associated with the eigenvalue $\lambda_j$ of $E$ and that

$$
1 < a_1 \leq \cdots \leq a_p.
$$

We also set $H_j = a_j^{-1}$ and have

$$
0 < H_p \leq \cdots \leq H_1 < 1.
$$

(12)

If $\lambda_j \in \mathbb{R}$, $J_j$ is a Jordan cell matrix of size $\tilde{l}_j = l_j \in \mathbb{N}\{0\}$. If $\lambda_j \in \mathbb{C}\setminus\mathbb{R}$, $J_j$ is a block of the form (11) of size $\tilde{l}_j = 2l_j \in 2\mathbb{N}\{0\}$. Then for any $t > 0$,

$$
t^E = P \begin{pmatrix}
t^{J_1} & 0 & \ldots & 0 \\
0 & t^{J_2} & 0 & \vdots \\
\vdots & \ddots & \ddots & 0 \\
0 & \ldots & 0 & t^{J_p}
\end{pmatrix} P^{-1}.
$$

We denote by $(e_1, \ldots, e_d)$ the canonical basis of $\mathbb{R}^d$ and set $f_j = Pe_j$ for every $j = 1, \ldots, d$. Hence, $(f_1, \ldots, f_d)$ is a basis of $\mathbb{R}^d$. For all $j = 1, \ldots, p$, let

$$
W_j = \text{span} \left( f_k; \sum_{i=1}^{j-1} \tilde{l}_i + 1 \leq k \leq \sum_{i=1}^{j} \tilde{l}_j \right).
$$

(13)

Then, each $W_j$ is a $E$-invariant set and $\mathbb{R}^d = \bigoplus_{j=1}^p W_j$.

The following result gives bounds on the growth rate of $\tau_E(x)$ in terms of the real parts of the eigenvalues of $E$. 
Proposition 3.3. For any $1 \leq k \leq p$, let $W_k$ be the $E$-invariant subspace of dimension $l_k$ or $2l_k$ associated with $H_k^{-1}$ by (13). Then, for any $r \in (0, 1)$ there exist some finite positive constant $c_1, c_2 > 0$ such that for every $1 \leq j_0 \leq j \leq p$,
\[
    c_1 \|x\|_{H_{j_0}} \log \|x\|^{-(p_{j_0,j}-1)H_{j_0}} \leq \tau_E(x) \leq c_2 \|x\|_{H_j} \log \|x\|^{(p_{j_0,j}-1)H_j}
\]
holds for any $x \in \Theta^j_{k=j_0} W_k \setminus \{0\}$ with $\|x\| \leq r$ and $p_{j_0,j} = \max_{j_0 \leq k \leq j} l_k$.

Proof. See the Appendix. □

Then, we easily deduce the following corollary.

Corollary 3.4. For any $1 \leq k \leq p$, let $W_k$ be the $E$-invariant subspace of dimension $l_k$ or $2l_k$ associated with $H_k^{-1}$ by (13). Then, for any $r \in (0, 1)$ there exist some finite positive constant $c_1, c_2 > 0$ such that for any $x \in W_j \setminus \{0\}$, $1 \leq j \leq p$, with $\|x\| \leq r$
\[
    c_1 \|x\|_{H_j} \log \|x\|^{-(l_j-1)H_j} \leq \tau_E(x) \leq c_2 \|x\|_{H_j} \log \|x\|^{(l_j-1)H_j}
\]
and for any $x \in \mathbb{R}^d \setminus \{0\}$ with $\|x\| \leq r$
\[
    c_1 \|x\|_{H_p} \log \|x\|^{-(l-1)H_p} \leq \tau_E(x) \leq c_2 \|x\|_{H_p} \log \|x\|^{(l-1)H_p},
\]
where $l = \max_{1 \leq j \leq p} l_j$.

Therefore we have precise estimates for the Hölder regularity of the radial part. Let us remark that we improve the first statement of Lemma 2.1 of [1] and that the second one can also be improved in a similar way. From these estimates we deduce the Hölder regularity of $X_\alpha$ in Section 5. As already mentioned, the study of the sample paths is based on a series representation. Then, before we state regularity properties, it remains to give the LePage series representation of harmonizable operator scaling stable random fields.

4. Representation as a LePage series

An overview on series representations of infinitely divisible distributions without Gaussian part can be found for example in [21,25] and references therein. In particular, LePage series representation [18,19] have been used in [26,14] to study the sample path regularity of some self-similar $\alpha$-stable random motions with $\alpha \in (0, 2)$. Here, this representation is also the main representation we use in the case $\alpha \in (0, 2)$. Actually, in the Gaussian case $\alpha = 2$, such representation does not hold.

Let us now introduce some notations we will use throughout the paper. Let $\mu$ be an arbitrary probability measure absolutely continuous with respect to the Lebesgue measure on $\mathbb{R}^d$ and let $m$ be its Radon–Nikodym derivative that is $\mu(d\xi) = m(\xi) \, d\xi$.

Notation. Let $(T_n)_{n \geq 1}$, $(g_n)_{n \geq 1}$ and $(\xi_n)_{n \geq 1}$ be independent sequences of random variables.

- $T_n$ is the $n$th arrival time of a Poisson process with intensity 1.
- $(g_n)_{n \geq 1}$ is a sequence of i.i.d. isotropic complex random variables so that $g_n \overset{(d)}{=} e^{i\theta} g_n$ for any $\theta \in \mathbb{R}$. We also assume that $0 < \mathbb{E}(|g_n|^2) < +\infty$.
- $(\xi_n)_{n \geq 1}$ is a sequence of i.i.d. random variables with common law $\mu(d\xi) = m(\xi) \, d\xi$.

According to Chapter 3 and Chapter 4 of [4], stochastic integrals with respect to an $\alpha$-stable random measure $\Lambda$ can be represented as a LePage series as soon as the control measure of $\Lambda$ is a finite measure. The next proposition generalizes this representation to a complex isotropic
α-stable random measure \( W_\alpha \) with Lebesgue control measure. It is a consequence of Lemma 4.1 of [26], which is a correction of Lemma 1.4 of [27]. This proposition can also be deduced from [21,20], which are concerned with series representations of stochastic integrals with respect to infinitely divisible random measures.

**Proposition 4.1.** Let \( \alpha \in (0, 2) \). Then, for every complex-valued function \( h \in L^\alpha (\mathbb{R}^d) \), the series
\[
Y^h = \sum_{n=1}^{+\infty} T_n^{-1/\alpha} m (\xi_n)^{-1/\alpha} h (\xi_n) g_n
\]
converges almost surely. Furthermore,
\[
C_\alpha Y^h = \int_{\mathbb{R}^d} h (\xi) W_\alpha (d\xi)
\]
with \( W_\alpha (d\xi) \) a complex isotropic \( \alpha \)-stable random measure on \( \mathbb{R}^d \) with Lebesgue control measure and
\[
C_\alpha = \mathbb{E} \left( |\mathcal{R} (g_1)|^\alpha \right)^{-1/\alpha} \left( \frac{1}{2\pi} \int_0^\pi |\cos (x)|^\alpha \, dx \right)^{1/\alpha} \left( \int_0^{+\infty} \sin (x) \frac{1}{x^\alpha} \, dx \right)^{-1/\alpha} \tag{14}
\]

**Remark 4.1.** According to **Proposition 4.1**, taking \( \alpha \in (0, 2) \), the random measure
\[
\Lambda_\alpha (d\xi) = C_\alpha \sum_{n=1}^{+\infty} T_n^{-1/\alpha} m (\xi_n)^{-1/\alpha} g_n \delta_{\xi_n} (d\xi)
\]
is a complex isotropic \( \alpha \)-stable random measure with Lebesgue control measure.

**Proof.** Let \( V_n = m (\xi_n)^{-1/\alpha} h (\xi_n) g_n \). Then, \( V_n, n \geq 1 \), are i.i.d. isotropic complex random variables. By Lemma 4.1 in [26], the series \( Y^h \) converges almost surely and
\[
\forall z \in \mathbb{C}, \quad \mathbb{E} \left( \exp \left( i \mathcal{R} \left( \bar{z} Y^h \right) \right) \right) = \exp (-\sigma^\alpha |z|^\alpha)
\]
with
\[
\sigma^\alpha = \mathbb{E} \left( |\mathcal{R} (V_1)|^\alpha \right) \int_0^{+\infty} \sin (x) \frac{1}{x^\alpha} \, dx.
\]
Since \( g_1 \) is invariant by rotation and independent with \( \xi_1 \),
\[
\mathbb{E} \left( |\mathcal{R} (V_1)|^\alpha \right) = \mathbb{E} \left( m (\xi_1)^{-1} |h (\xi_1)|^\alpha \right) \mathbb{E} \left( |\mathcal{R} (g_1)|^\alpha \right) = \mathbb{E} \left( |\mathcal{R} (g_1)|^\alpha \right) \int_{\mathbb{R}^d} |h (\xi)|^\alpha \, d\xi.
\]
Moreover, by definition of an isotropic \( \alpha \)-stable random measure (see [4]),
\[
\forall z \in \mathbb{C}, \quad \mathbb{E} \left( \exp \left( i \mathcal{R} \left( \bar{z} \int_{\mathbb{R}^d} h (\xi) W_\alpha (d\xi) \right) \right) \right) = \exp (-c_\alpha^\alpha (h) |z|^\alpha)
\]
with \( c_\alpha^\alpha (h) = \left( \frac{1}{2\pi} \int_0^\pi |\cos (x)|^\alpha \, dx \right) \int_{\mathbb{R}^d} |h (\xi)|^\alpha \, d\xi \). Then,
\[
\forall z \in \mathbb{C}, \quad \mathbb{E} \left( \exp \left( i \mathcal{R} \left( C_\alpha \bar{z} Y^h \right) \right) \right) = \exp (-c_\alpha^\alpha (h) |z|^\alpha) = \mathbb{E} \left( \exp \left( i \mathcal{R} \left( \bar{z} \int_{\mathbb{R}^d} h (\xi) W_\alpha (d\xi) \right) \right) \right)
\]
with $C_\alpha$ defined by (14). This implies that

$$C_\alpha Y^h \overset{(d)}{=} \int_{\mathbb{R}^d} h(\xi) \, W_\alpha(d\xi),$$

which concludes the proof. □

From the previous proposition, we deduce the following statement which is the main series representation we use in our investigation.

**Proposition 4.2.** Let $\alpha \in (0, 2)$. For every $x \in \mathbb{R}^d$, the series

$$Y_\alpha(x) = C_\alpha \mathcal{R} \left( \sum_{n=1}^{+\infty} T_n^{-1/\alpha} m(\xi_n)^{-1/\alpha} f(x, \xi_n) g_n \right),$$

where $f$ is defined by (5) and $C_\alpha$ by (14), converges almost surely. Furthermore,

$$\left\{ Y_\alpha(x); x \in \mathbb{R}^d \right\} \overset{(fdd)}{=} \left\{ X_\alpha(x); x \in \mathbb{R}^d \right\},$$

where $X_\alpha$ is defined by (3).

**Proof.** From Proposition 4.1, for any $x \in \mathbb{R}^d$, the convergence of the series follows from the fact that $f(x, \cdot) \in L^\alpha_\alpha(\mathbb{R}^d)$. The equality of finite dimensional distributions between $X_\alpha$ and $Y_\alpha$ is obtained by linearity of the integral and the sum, which define the fields, and Proposition 4.1. □

Using LePage representation (15) of $X_\alpha$ and the estimates given in Section 3, we give an upper bound for the modulus of continuity of $X_\alpha$ and obtain the critical Hölder regularity of its sample paths in the next section.

5. Hölder regularity and Hausdorff dimension

Throughout this section we fix $K$ a non-empty compact set of $\mathbb{R}^d$ and investigate the Hölder regularity on $K$ of the harmonizable operator scaling stable random field $X_\alpha$ defined by (3).

Let us recall that for the Gaussian case $\alpha = 2$, according to Theorem 5.4 of [1], the Hölder regularity of $X_2$ depends on the subspaces $(W_j)_{1 \leq j \leq p}$ defined by (13) and associated with the eigenvalues of $E$. More precisely, Theorem 5.4 of [1] implies that, when restricted to the subspace $W_j$, the Gaussian random field $\{X_2(x); x \in W_j\}$ admits $H_j$ as critical Hölder exponent. This follows from the fact that the regularity of $X_2$ on $W_j$ is determined by the regularity of $\tau_E$ around 0 on $W_j$. Here, we give an upper bound for the modulus of continuity of $X_\alpha$ in the general case $\alpha \in (0, 2)$. Then we prove that the critical Hölder exponents are the same as in the Gaussian case $\alpha = 2$. Let us state our main result when $\alpha \in (0, 2)$.

**Theorem 5.1.** Let $\alpha \in (0, 2)$ and $X_\alpha$ be defined by (3). Then, there exists a modification $X_\alpha^*$ of $X_\alpha$ on $K$ such that, with $\tau_E$ defined by (9), for any $\varepsilon > 0$

$$\lim_{\delta \downarrow 0} \sup_{x, y \in K, 0 < |x - y| | \delta} \frac{|X_\alpha^*(x) - X_\alpha^*(y)|}{\tau_E(x - y) |\log \tau_E(x - y)|^{1/\alpha + 1/2 + \varepsilon}} = 0 \quad \text{almost surely.}$$

(16)

This result was proved in the case of harmonizable self-similar stable processes in [14], i.e. in the case of Example 2.1 with $d = 1$. The main idea is to use the LePage series representation (15)
where \( g_n, n \geq 1 \), are Gaussian complex isotropic random variables. It remains to choose the density distribution \( m \) of \( \xi_n \). In [14], the authors choose

\[
m(\xi) = \frac{c_\eta}{|\xi| |\log |\xi||^{1+\eta}}, \quad \xi \in \mathbb{R}\backslash\{0\}
\]

where \( c_\eta > 0 \). A straightforward generalization in higher dimension \( d \) leads to choose

\[
m(\xi) = \frac{c_\eta}{||\xi||^d |\log ||\xi|||^{1+\eta}}, \quad \xi \in \mathbb{R}^d\backslash\{0\}.
\]

Remark that in this case (i.e. Example 2.1) the matrix \( E = I_d/H = E' \) and that we can choose \( \|\cdot\|_{E'} = \|\cdot\| \). Then, using classical polar coordinates, we obtain that for all \( x \neq 0 \),

\[(\tau_{E'}(x), \ell_{E'}(x)) = \left( \|x\|^H, \frac{x}{\|x\|} \right)\]

and therefore that

\[
m(\xi) = \frac{c_\eta}{\tau_{E'}(\xi)^d |\log \tau_{E'}(\xi)|^{1+\eta}}
\]

since \( q = \text{trace}(E) = d/H \). Note that by this way \( m \) only depends on the radial part \( \tau_{E'} \).

**Proof of Theorem 5.1.** We can assume without loss of generality that \( K = [0,1]^d \). According to Proposition 4.2, for every \( x \in \mathbb{R}^d \)

\[
Y_\alpha(x) = C_\alpha \Re \left( \sum_{n=1}^{+\infty} T_n^{-1/\alpha} m(\xi_n)^{-1/\alpha} f(x, \xi_n) g_n \right)
\]

converges almost surely and \( Y_\alpha \overset{(fdd)}{=} X_\alpha \). As already mentioned, we assume that \( g_n, n \geq 1 \) are Gaussian complex isotropic random variables. Moreover, we choose as density distribution of \( \xi_n \)

\[
m(\xi) = \frac{c_\eta}{\tau_{E'}(\xi)^d |\log \tau_{E'}(\xi)|^{1+\eta}}, \quad \xi \in \mathbb{R}^d\backslash\{0\},
\]

(17)

where \( \tau_{E'}(\xi) \) is given by (9), \( \eta > 0 \) and \( c_\eta > 0 \) is such that \( \int_{\mathbb{R}^d} m(\xi) \, d\xi = 1 \).

As in the proof of the Kolmogorov–Centsov Theorem (see [28]), we exhibit \((x_k)_k\) a countable dense sequence of elements of \( K \) and a finite positive constant \( C \) such that for \( \tau_E(x_k - x_{k'}) \) small enough,

\[
|Y_\alpha(x_k) - Y_\alpha(x_{k'})| \leq C \tau_E(x_k - x_{k'}) |\log \tau_E(x_k - x_{k'})|^{1/\alpha+1/2+\varepsilon}
\]

almost surely. Then, \( X_\alpha \) satisfies the same property. Finally, we give a modification \( X_\alpha^* \) of \( X_\alpha \) for which (16) holds. In the first step, we construct the sequence \((x_k)_k\) and state some useful properties of this sequence.

**Step 1.** Let \( r \in (0,1) \). By Corollary 3.4, there exist a finite positive constant \( c_2 \) and \( l \in \mathbb{N}\backslash\{0\} \) such that

\[
\tau_E(x) \leq c_2 \|x\|^H_p |\log \|x\||^{(l-1)H_p},
\]

(18)

for any \( x \in \mathbb{R}^d\backslash\{0\} \) with \( \|x\| \leq r \). Up to change \( c_2 \) in (18), we can assume that

\[
c_2 d^{H_p/2} 2^{-H_p} (\log 2)^{(l-1)H_p} > 1.
\]

(19)
For any $k \in \mathbb{N} \setminus \{0\}$, let us choose $v_k \in \mathbb{N} \setminus \{0\}$ the smallest positive integer such that
\[ c_2 d^{H_p/2} 2^{-v_k H_p} (v_k \log 2)^{(l-1)H_p} \leq 2^{-k}. \]
This implies that $\lim_{k \to +\infty} v_k = +\infty$. Moreover, the definition of $v_k$ and (19) imply that $v_k > 1$ for every $k \in \mathbb{N} \setminus \{0\}$. Therefore, for every $k \in \mathbb{N} \setminus \{0\}$, since $1 \leq v_k - 1 < v_k$, the definition of $v_k$ leads to
\[ c_2 d^{H_p/2} 2^{-v_k H_p} ((v_k - 1) \log 2)^{(l-1)H_p} > 2^{-k}. \]
Hence,
\[ 2^{-k} \left( 2\sqrt{d} \right)^{-H_p} c_2^{-1} < \left( 2^{-v_k} (v_k \log 2)^{l-1} \right)^{H_p} \leq 2^{-k} \left( \sqrt{d} \right)^{-H_p} c_2^{-1}. \]
Then, since $\lim_{k \to +\infty} v_k = +\infty$, considering the logarithm of each member of (21), one easily proves that
\[ \lim_{k \to +\infty} \frac{k}{v_k} = H_p. \]

Hence, there exist two positive finite constants $c_3, c_4$ such that
\[ \forall k \in \mathbb{N} \setminus \{0\}, \quad c_3 2^{k/H_p} k^{l-1} \leq 2^{v_k} \leq c_4 2^{k/H_p} k^{l-1}. \]
For every $k \in \mathbb{N} \setminus \{0\}$ and $j = (j_1, \ldots, j_d) \in \mathbb{Z}^d$ we set
\[ x_{k,j} = \frac{j}{2^{v_k}}, \quad \text{and} \quad \mathcal{D}_k = \left\{ x_{k,j} : j \in \mathbb{Z}^d \cap \left[ 0, 2^{v_k} \right]^d \right\}. \]
Let us remark that the sequence $(\mathcal{D}_k)_k$ is increasing and set $\mathcal{D} = \bigcup_{k=1}^{+\infty} \mathcal{D}_k$.

Let us now prove that for $k$ large enough, $\mathcal{D}_k$ is a $2^{-k}$ net of $K$ for $\tau_E$ in the sense that for any $x \in K$ one can find $x_{k,j} \in \mathcal{D}_k$ such that $\tau_E(x - x_{k,j}) \leq 2^{-k}$. Let us fix $x \in K$ and choose $j_i$ such that $j_i \leq 2^{v_k} x_i < j_i + 1$ for $1 \leq i \leq d$. Without loss of generality, we can assume that $x \not\in \mathcal{D}_k$. Then, $0 < \| x - x_{k,j} \| \leq 2^{-v_k} \sqrt{d}$ and since $\lim_{k \to +\infty} v_k = +\infty$, for $k$ large enough,
\[ \| x - x_{k,j} \| \leq 2^{-v_k} \sqrt{d} \leq r. \]
Hence, since $t \mapsto t^{H_p} (\log(t))^{(l-1)H_p}$ is an increasing function on $(0, e^{1-l}]$, (18) and (20) imply that
\[ \tau_E(x - x_{k,j}) \leq 2^{-k} \]
for $k$ large enough. Then, for $k$ large enough, $\mathcal{D}_k$ is a $2^{-k}$ net of $K$ for $\tau_E$.

**Step 2.** Almost surely, for any $x, y \in \mathcal{D}$
\[ Y_{\alpha}(x) - Y_{\alpha}(y) = C_{\alpha} \mathcal{R} \left( \sum_{n=1}^{+\infty} T_n^{-1/\alpha} m(\xi_n)^{-1/\alpha} (f(x, \xi_n) - f(y, \xi_n)) g_n \right), \]
where $C_{\alpha}$ is defined by (14) and $f$ by (5). Let us consider the random variable
\[ R(x, y) = \sum_{n=1}^{+\infty} T_n^{-1/\alpha} m(\xi_n)^{-1/\alpha} (f(x, \xi_n) - f(y, \xi_n)) g_n. \]
Therefore, for every

\[ Y_\alpha(x) - Y_\alpha(y) = C_\alpha \mathbb{R}(R(x, y)) \]

almost surely.

Therefore, conditionally to \((T_n, \xi_n), Y_\alpha(x) - Y_\alpha(y)\) is a real centered Gaussian random variable with variance

\[
v^2((x, y) | (T_n, \xi_n)) = \frac{C_\alpha^2}{2} \mathbb{E}
\left( |R(x, y)|^2 | (T_n, \xi_n) \right)
= \frac{C_\alpha^2}{2} \mathbb{E}(|g_1|^2) \sum_{n=1}^{+\infty} T_n^{-2/\alpha} m(\xi_n)^{-2/\alpha} |f(x - y, \xi_n)|^2,
\]

since \(|f(x, \xi_n) - f(y, \xi_n)| = |f(x - y, \xi_n)|

As in [15], let

\[ \varphi(t) = \sqrt{2Ad \log \frac{1}{t}}, \quad 0 < t < 1 \]

(24)

where \(A\) is a finite positive constant such that \(A > 2/H_p - 1/H_1\).

For \(k \in \mathbb{N}\backslash\{0\}\), we consider

\[
E_{i,j}^k = \{ \omega : |Y_\alpha(x_{k,i}) - Y_\alpha(x_{k,j})| > v \left( (x_{k,i}, x_{k,j}) | (T_n, \xi_n) \right) \varphi(\tau_E(x_{k,i} - x_{k,j})) \}
\]

for any \((i, j) \in \mathbb{Z}^d \times \mathbb{Z}^d, i \neq j\), such that \(\tau_E(x_{k,i} - x_{k,j}) < 1\). Then,

\[
\mathbb{P}(E_{i,j}^k) = \mathbb{E}
\left( \mathbb{E}(1_{E_{i,j}^k} | (T_n, \xi_n)) \right).
\]

(25)

Let us give an upper bound of this probability for a well chosen \((k, i, j)\). Let \(Z\) be a real centered Gaussian random variable with variance 1. Then, (25) implies that

\[
\mathbb{P}(E_{i,j}^k) = \mathbb{P}(|Z| > \varphi(\tau_E(x_{k,i} - x_{k,j}))).
\]

Let us choose \(\delta \in (0, 1)\) and set for \(k \in \mathbb{N}\backslash\{0\},

\[
\delta_k = 2^{-(1-\delta)k} \quad \text{and} \quad I_k = \left\{(i, j) \in \left(\mathbb{Z}^d \cap [0, 2^{\nu_k}]^d\right)^2 : 0 < \tau_E(x_{k,i} - x_{k,j}) \leq \delta_k\right\}.
\]

(26)

For every \((i, j) \in I_k\), since \(\varphi\) is a decreasing function

\[
\mathbb{P}(|Z| > \varphi(\tau_E(x_{k,i} - x_{k,j}))) \leq \mathbb{P}(|Z| > \varphi(\delta_k)).
\]

We recall that

\[
\forall u \geq 0, \quad \mathbb{P}(Z > u) \leq \frac{e^{-u^2/2}}{\sqrt{2\pi u}}.
\]

Therefore, for every \(k \in \mathbb{N}\backslash\{0\}\) and \((i, j) \in I_k\),

\[
\mathbb{P}(E_{i,j}^k) \leq \sqrt{\frac{2}{\pi}} \frac{e^{-\varphi^2(\delta_k)/2}}{\varphi(\delta_k)} = \frac{2^{-(1-\delta)kAd}}{\sqrt{\pi Ad (1-\delta) k \log 2}}
\]
since \( \delta_k = 2^{-(1-\delta)k} \). Hence,
\[
\sum_{k=1}^{\infty} \sum_{(i,j) \in I_k} \mathbb{P} \left( E_{i,j}^k \right) \leq \frac{1}{\sqrt{\pi Ad (1-\delta)}} \log 2 \sum_{k=1}^{\infty} 2^{-(1-\delta)kAd} \text{card}(I_k).
\]

Let us give an upper bound of \( \text{card}(I_k) \). First, let us remark that one can find a finite positive constant \( c_5 \) such that, for any \( k \in \mathbb{N} \setminus \{0\} \) and any \( x \in \mathbb{R}^d \setminus \{0\} \) satisfying \( \tau_E(x) \leq \delta_k \),
\[
||x|| \leq c_5 \tau_E(x) (1/H_l) |\log \tau_E(x)|^{l-1}.
\]
This inequality is established in the proof of Proposition 3.3, see Eq. (35). Then, since \( t \mapsto t^{1/H_l} |\log t|^{l-1} \) is an increasing function on \((0, r_0)\), for a well chosen \( r_0 \), there exists a finite positive constant \( c_6 \) such that for any \( k \in \mathbb{N} \setminus \{0\} \) and any \( x \in \mathbb{R}^d \setminus \{0\} \) satisfying \( \tau_E(x) \leq \delta_k \),
\[
||x|| \leq c_6 \delta_k^{1/H_l} |\log \delta_k|^{l-1} = ((1 - \delta) \log 2)^{l-1} c_6 \delta_k^{1/H_l} k^{l-1}.
\]
Hence, one can find a finite positive constant \( C > 0 \) such that for any \( k \in \mathbb{N} \setminus \{0\} \) and any \( i \in \mathbb{Z}^d \cap [0, 2^v]^d \),
\[
\text{card} \left\{ j \in \mathbb{Z}^d \cap [0, 2^v]^d : (i, j) \in I_k \right\} \leq C \left( \delta_k^{1/H_l} 2^v k^{l-1} \right)^d.
\]
By definition of \( I_k \), for every \( k \in \mathbb{N} \setminus \{0\} \),
\[
\text{card} I_k \leq C (2^v + 1)^d \delta_k^{d/H_l} 2^{dv_k} k^{d(l-1)}.
\]
Then, by (22), there exists a finite constant \( C > 0 \) such that for all \( k \in \mathbb{N} \setminus \{0\} \),
\[
\text{card} I_k \leq C \delta_k^{d/H_l} 2^{kd/H_p} k^{d(l-1)}.
\]
Hence, since \( \delta_k = 2^{-(1-\delta)k} \)
\[
\sum_{k=1}^{\infty} \sum_{(i,j) \in I_k} \mathbb{P} \left( E_{i,j}^k \right) \leq \frac{C}{\sqrt{A (1-\delta)}} \sum_{k=1}^{\infty} k^{3d(l-1)} 2^{-kd} \left( -\frac{2}{H_p} + \frac{1}{H_l} + (1-\delta)A \right)
\]
with \( C > 0 \) a finite positive constant. Since \( A > \frac{2}{H_p} - \frac{1}{H_l} \), choosing \( \delta \) small enough, the last inequality implies that
\[
\sum_{k=1}^{\infty} \sum_{(i,j) \in I_k} \mathbb{P} \left( E_{i,j}^k \right) < +\infty.
\]
By the Borel–Cantelli lemma, almost surely there exists an integer \( k^* (\omega) \) such that for every \( k \geq k^* (\omega) \),
\[
|Y_\alpha (x) - Y_\alpha (y)| \leq v \left( (x, y) \mid (T_n, \xi_n)_n \right) \varphi \left( \tau_E (x - y) \right)
\]
for all \( x, y \in D_k, x \neq y \), with \( \tau_E (x - y) \leq \delta_k \).

**Step 3.** As in [14] let us give an upper bound of the conditional variance \( v^2 \left( (x, y) \mid (T_n, \xi_n)_n \right) \), defined by (23), with respect to \( \tau_E (x - y) \). Since \( f \) is defined by (5)
\[
v^2 \left( (x, y) \mid (T_n, \xi_n)_n \right) \leq \frac{C_2}{2} \mathbb{E} \left[ |g_1|^2 \right] \sigma^2 (\tau_E (x - y)),
\]
where, for all \( h \geq 0 \),
\[
\sigma^2 (h) = \sum_{n=1}^{+\infty} T_n^{-2/\alpha} m (\xi_n)^{-2/\alpha} \min \left( M_E \left\| h E^i \xi_n \right\|, 2 \right)^2 \psi (\xi_n)^{-2-2q/\alpha},
\]
(28)
with \( M_E \) defined by (10) and \( m \) by (17). For the sake of clearness we postpone the proof of the control of \( \sigma^2(h) \) in Appendix and state it in the following lemma.

**Lemma 5.2.** Let \( \eta > 0, m \) be the density probability associated with \( \eta \) by (17) and \( \sigma^2 \) be defined by (28) with \( M_E \) given by (10). For any \( \gamma \in (0, 1) \) there exists a finite constant \( c > 0 \) such that for all \( h \in (0, 1 - \gamma) \),

\[
\mathbb{E} \left( \sigma^2(h) \mid (T_n)_n \right) \leq c \sum_{n=1}^{+\infty} T_n^{-2/\alpha} h^2 \| \log h \|^{(1+\eta)(2/\alpha-1)} \quad \text{almost surely.}
\]

Following [14] let us denote

\[ b(h) = h \| \log h \|^{(1+\eta)/\alpha}. \]

Then by Lemma 5.2,

\[
\mathbb{E} \left( \sum_{k=1}^{+\infty} \frac{\sigma^2(2^{-k})}{b^2(2^{-k})} \right) (T_n)_n < +\infty \quad \text{almost surely.}
\]

Therefore by independence of \((T_n)_n\) and \((\xi_n)_n\), almost surely

\[
\lim_{k \to +\infty} \frac{\sigma^2(2^{-k})}{b^2(2^{-k})} = 0.
\]

Up to change the Euclidean norm \( \| \cdot \| \) by the equivalent norm \( \| \cdot \|_{E'} \) defined in Lemma 6.1.5 of [17] the map \( h \mapsto \| h^{E'} \xi \| \) is increasing and so is \( h \mapsto \sigma^2(h) \). Also, one can conclude, as in [14], that almost surely

\[
\lim_{h \to 0} \frac{\sigma^2(h)}{b^2(h)} = 0.
\]

Therefore, up to change \( k^* \), (24) and (27) imply that for every \( k \geq k^*(\omega) \),

\[
|Y_\alpha(x) - Y_\alpha(y)| \leq \sqrt{2dA} \tau_E(x - y) \| \log \tau_E(x - y) \|^{(1+\eta)/\alpha+1/2}
\]

for all \( x, y \in D_k \) such that \( 0 < \tau_E(x - y) \leq \delta_k \), with \( \delta_k \) defined by (26). Let

\[
\Omega^* = \bigcup_{n=1}^{+\infty} \bigcap_{k \geq n} \bigcap_{x, y \in D_k} \{ |X_\alpha(x) - X_\alpha(y)| \}
\]

\[
\leq \sqrt{2dA} \tau_E(x - y) \| \log \tau_E(x - y) \|^{(1+\eta)/\alpha+1/2}.
\]

Since \( X_\alpha \) and \( Y_\alpha \) have the same finite dimensional distributions, \( \mathbb{P}(\Omega^*) = 1 \).

**Step 4.** Let us now define a modification \( X^{*}_\alpha \) of \( X_\alpha \) that satisfies (29) for all \( x, y \in K \) with \( \tau_E(x - y) \) small enough and some constant \( C > 0 \) instead of \( \sqrt{2dA} \). Let \( \omega \in \Omega^* \), by Step 3 there exists \( k^*(\omega) \geq 1 \) such that \( X_\alpha \) satisfies (29) for \( k \geq k^*(\omega) \), \( x, y \in D_k \) and \( 0 < \tau_E(x - y) \leq \delta_k \) with \( \delta_k \) defined by (26).

Let us recall that by Lemma 2.2 of [1], there exists a finite constant \( K_E \geq 1 \) such that for all \( x, y \in \mathbb{R}^d \)

\[
\tau_E(x + y) \leq K_E (\tau_E(x) + \tau_E(y)).
\]

Therefore, \( \tau_E(x + y) \leq K_E \tau_E(x) \) for all \( x, y \in \mathbb{R}^d \) with \( \tau_E(x) < 1 \).
Let
\[ F(h) = \sqrt{2dAh} |\log h|^{(1+\eta)/\alpha+1/2}, \quad h > 0 \]  
and \( k_0 \in \mathbb{N} \setminus \{0\} \) such that \( 2^{k_0}\delta_{k_0+1} < 3K^2_E \) and \( F \) is increasing on \((0, \delta_{k_0}]\). Up to change \( k^*(\omega) \), we can assume that \( k^*(\omega) \geq k_0 \).

Let \( x, y \in \mathcal{D} \) such that \( x \neq y \) and \( 3K^2_E \tau_E (x - y) \leq \delta_{k^*(\omega)} \). Then, there exists a unique \( k \geq k^*(\omega) \) such that \( \delta_{k+1} < 3K^2_E \tau_E (x - y) \leq \delta_k \). Furthermore, since \( x, y \in \mathcal{D} \), one can find \( n \geq k + 1 \) such that \( x, y \in \mathcal{D}_n \). Moreover, by Step 1, up to change \( k^*(\omega) \), for \( j = k, \ldots, n - 1 \), we can choose \( x(j), y(j) \in \mathcal{D}_j \) such that
\[ \tau_E (x - x(j)) \leq 2^{-j} \quad \text{and} \quad \tau_E (y - y(j)) \leq 2^{-j}. \]

By construction \( \tau_E (x(k) - y(k)) \leq K^2_E (\tau_E (x - y) + 2^{1-k}) \). Let us point out that since \( k \geq k_0 \), \( 2^k \delta_{k+1} \geq 2^{k_0} \delta_{k_0+1} > 3K^2_E \). Therefore, one easily sees that \( 2^{-k} < \frac{\delta_{k+1}}{3K^2_E} < \tau_E (x - y) \) and gets
\[ \tau_E (x(k) - y(k)) \leq 3K^2_E \tau_E (x - y). \]

On the one hand, by Step 3, \( 3K^2_E \tau_E (x - y) \leq \delta_k \) implies that
\[ |X_\alpha (x(k)) - X_\alpha (y(k))| \leq F (\tau_E (x(k) - y(k))). \]

On the other hand we can write
\[ X_\alpha (x) - X_\alpha (x(k)) = \sum_{j=k}^{n-1} (X_\alpha (x(j+1)) - X_\alpha (x(j))) \]
with \( \tau_E (x(j+1) - x(j)) \leq 3K^2_E 2^{-(j+1)} \leq \delta_{j+1} \) since \( j \geq k_0 \). Moreover, note that \( x(j) \in \mathcal{D}_j \subset \mathcal{D}_{j+1} \) and Step 3 again implies that
\[ |X_\alpha (x) - X_\alpha (x(k))| \leq \sum_{j=k}^{n-1} F (\tau_E (x(j+1) - x(j))) \leq CF(\delta_{k+1}), \]
where \( C = \sum_{j=0}^{+\infty} (j + 1)^{(1+\eta)/\alpha+1/2} \delta_j < +\infty \). With similar computations for \( X_\alpha (y) - X_\alpha (y(k)) \), we get
\[ |X_\alpha (x) - X_\alpha (y)| \leq F (\tau_E (x(k) - y(k))) + 2CF (\delta_{k+1}) \leq (1 + 2C)F (3K^2_E \tau_E (x - y)). \]

Therefore, since \( F \) is defined by \( (30) \), one can find a finite constant \( C > 0 \) such that for all \( x, y \in \mathcal{D} \) satisfying \( 0 < 3K^2_E \tau_E (x - y) \leq \delta_{k^*(\omega)} \),
\[ |X_\alpha (x) - X_\alpha (y)| \leq C \tau_E (x - y) |\log \tau_E (x - y)|^{(1+\eta)/\alpha+1/2}. \]

(31)

We now give a modification of \( X_\alpha \). For \( x \in \mathcal{D} \), we set
\[ X_\alpha^* (x)(\omega) = X_\alpha (x)(\omega). \]
For \( x \in K \), let \( x^{(n)} \in \mathcal{D} \) be such that \( \lim_{n \to +\infty} x^{(n)} = x \). In view of (31), \( (X^*_\alpha (x^{(n)})(\omega))_n \) is a Cauchy sequence and then converges. We set

\[
X^*_\alpha (x)(\omega) = \lim_{n \to +\infty} X^*_\alpha (x^{(n)})(\omega).
\]

Remark that this limit does not depend on the choice of \( (x^{(n)}) \). Moreover, since \( X_\alpha \) is stochastically continuous, \( X^*_\alpha \) is a modification of \( X_\alpha \). Finally, by continuity of \( \tau_E \), we easily see that

\[
|X^*_\alpha (x)(\omega) - X^*_\alpha (y)(\omega)| \leq C \tau_E (x - y) |\log \tau_E (x - y)|^{(1+\alpha)/\alpha+1/2}
\]

for all \( x, y \in K \) such that \( 0 < 3K^2 \tau_E (x - y) < \delta_{k^*(\omega)} \), which concludes the proof. \( \square \)

Following the same lines as the proof of Theorem 5.1 we obtain a similar result for a class of Gaussian random fields including the operator scaling ones defined in [1] \( (\alpha = 2) \). Let us remark that \( Y_\alpha \) is not defined for \( \alpha = 2 \). However, in Step 2 of the proof, let us replace \( Y_\alpha \) by \( X \) a centered Gaussian random field and \( v^2 ((x, y) \mid (T_n, \xi_n)_{n}) \) by the variance of \( X(x) - X(y) \)

\[
v^2 ((x, y)) = \mathbb{E} ((X(x) - X(y))^2).
\]

Furthermore let us replace Step 3 by the assumption that for some \( \beta \in \mathbb{R} \) and \( \delta_0 > 0 \) there exists a finite constant \( C > 0 \) such that for \( x, y \in K \) with \( 0 < \tau_E (x - y) \leq \delta_0 \),

\[
\mathbb{E} ((X(x) - X(y))^2) \leq C \tau_E (x - y)^2 |\log \tau_E (x - y)|^\beta.
\]

Then Step 1, Step 2 and Step 4 yield the following proposition.

**Proposition 5.3.** Let \( X = (X(x))_{x \in \mathbb{R}^d} \) be a centered Gaussian random field satisfying (32) for some \( \beta \in \mathbb{R} \). There exists a modification \( X^* \) of \( X \) on \( K \) such that

\[
\lim_{\delta \downarrow 0} \sup_{\substack{x, y \in K \\
0 < \|x - y\| \leq \delta}} \frac{|X^*(x) - X^*(y)|}{\tau_E (x - y) |\log \tau_E (x - y)|^{1/2+\beta+\varepsilon}} = 0 \quad \text{almost surely}
\]

for any \( \varepsilon > 0 \) and with \( \tau_E \) defined by (9).

**Remark 5.1.** Let us point out that if \( X_2 \) is an operator scaling Gaussian random field as defined in [1], then

\[
\mathbb{E} ((X_2(x) - X_2(y))^2) = \tau_E (x - y)^2 \mathbb{E} (X_2 (\ell_E (x - y))^2)
\]

and \( X_2 \) satisfies (32) with \( \beta = 0 \) according to Eq. (5.2) of [1]. Therefore Proposition 5.3 is more precise than one could expect from Theorem 5.1, replacing \( \alpha \) by 2.

Let us also mention that [29] gives a different proof of a similar result for some Gaussian operator scaling random fields with stationary increments.

For all \( j = 1, \ldots, p \) we set \( K_j = K \cap \bigoplus_{k=1}^j W_k \), where \( W_k \) is the \( E \)-invariant subspace of dimension \( l_k \) or \( 2l_k \) associated with \( H_k^{-1} \) by (13). Note that \( K_p = K \).
Corollary 5.4. Let $\alpha \in (0, 2]$ and $X_\alpha$ be defined by (3). There exists a modification $X^*_\alpha$ of $X_\alpha$ on $K$ such that for all $j = 1, \ldots, p$ and any $\varepsilon > 0$, 

$$
\lim_{\delta \downarrow 0} \sup_{x, y \in K_j, 0 < |x - y| \leq \delta} \frac{|X^*_\alpha(x) - X^*_\alpha(y)|}{x - y\| H_j \log \| x - y \|^{H_j(p_j - 1) + \beta + 1/2 + \varepsilon}} = 0 \quad \text{almost surely},
$$

with $p_j = \max_{1 \leq k \leq j} l_k$, $\beta = 1/\alpha$ if $\alpha \neq 2$ and $\beta = 0$ if $\alpha = 2$.

Proof. It follows from Theorem 5.1, Propositions 5.3 and 3.3, since $a_j \leq a_p$ for any $j = 1 \ldots p$. □

Corollary 5.5. Let $\alpha \in (0, 2]$ and $X_\alpha$ be defined by (3). There exists a modification $X^*_\alpha$ of $X_\alpha$ which has locally $H$-Hölder sample paths on $\mathbb{R}^d$ for every $H \in (0, H_p)$.

Proof. It is a simple consequence of Corollary 5.4. □

Now, as in [1], we are looking for global and directional Hölder critical exponents of the harmonizable stable random field $X_\alpha$. These exponents have been introduced in [9] in the Gaussianrealm but can be defined for any random field, see [1]. Let us first recall Definition 5.1 of [9] which introduces the global Hölder critical exponent of a random field.

Definition 5.1. Let $H \in (0, 1)$. A real-valued random field $(X(x))_{x \in \mathbb{R}^d}$ is said to have Hölder critical exponent $H$ if there exists a modification $X^*$ of $X$ that satisfies the following two properties:

(i) for any $s \in (0, H)$, the sample paths of $X^*$ satisfy almost surely a uniform Hölder condition of order $s$ on any compact set, i.e. for any compact set $K' \subset \mathbb{R}^d$, there exists a finite positive random variable $A$ such that almost surely

$$
|X^*(x) - X^*(y)| \leq A \| x - y \|^s \quad \text{for all } x, y \in K'
$$

(ii) for any $s \in (H, 1)$, almost surely the sample paths of $X^*$ fail to satisfy any uniform Hölder condition of order $s$.

Remark 5.2. Note that the Hölder critical exponent, if it exists, is well-defined since any continuous modification of $X$ and $X^*$ are indistinguishable.

Moreover, according to Definition 5.3 of [9], the directional regularities of a random field $X$ are defined as follows.

Definition 5.2. Let $S^{d-1}$ be the Euclidean unit sphere. A real-valued random field $X = (X(x))_{x \in \mathbb{R}^d}$ admits $H(u)$ as directional regularity in direction $u \in S^{d-1}$ if the process $(X(tu))_{t \in \mathbb{R}}$ admits $H(u)$ as Hölder critical exponent.

Now let us give the directional and global Hölder critical exponents of $X_\alpha$.

Proposition 5.6. The random field $X_\alpha$ admits $H_p$ as Hölder critical exponent. Moreover, for any $j = 1, \ldots, p$, if $u \in W_j \cap S^{d-1}$, with $W_j$ defined by (13) and $S^{d-1}$ the Euclidean unit sphere of $\mathbb{R}^d$, the random field $X_\alpha$ admits $H_j$ as directional regularity in the direction $u$.

Proof. For $Z$ a real SàS random variable we let

$$
\|Z\|_\alpha = (-\log (\mathbb{E} (\exp (i Z))))^{1/\alpha}.
$$
Let $\tau_E$ and $I_E$ be defined by (9). Then, for any $x, y \in \mathbb{R}^d, x \neq y$,
\[ \|X_\alpha^*(x) - X_\alpha^*(y)\|_\alpha = D_\alpha (\ell_E(x - y)) \tau_E(x - y) \]
where for all $\theta \in S_E$,
\[ D_\alpha (\theta) = \left( d_\alpha \int_{\mathbb{R}^d} \left| e^{i(\theta, \xi)} - 1 \right|^\alpha \psi(\xi)^{-\alpha - q} d\xi \right)^{1/\alpha} \quad \text{with} \quad d_\alpha = \frac{1}{2\pi} \int_0^\pi |\cos(t)|^\alpha \, dt. \]
From Lebesgue’s Theorem, the function $D_\alpha$ is continuous on the compact set $S_E$, with positive values. Let us denote $m_\alpha = \min_{\theta \in S_E} D_\alpha (\theta) > 0$.

Let $u \in W_j \cap S^{d-1}$ with $1 \leq j \leq p$. According to Corollary 3.4, for $|t - t'|$ small enough,
\[ \|X_\alpha^*(tu) - X_\alpha^*(t'u)\|_\alpha \geq m_\alpha c_1 |t - t'|^{H_j} \log |t - t'|^{-(l_j - 1)H_j}. \]
Therefore, for any $s > H_j$, it implies that $\frac{X_\alpha^*(tu) - X_\alpha^*(t'u)}{|t - t'|^s}$ is almost surely unbounded as $|t - t'| \downarrow 0$. Then, almost surely, $\left( X_\alpha^*(tu) \right)_{t \in \mathbb{R}}$ does not satisfy (33) on $[0, 1]$.

Moreover, Corollary 5.4 implies that $\left( X_\alpha^*(tu) \right)_{t \in \mathbb{R}}$ satisfies (33) on any non-empty compact set $K' \subset \mathbb{R}^d$ for any $s < H_j$. Thus $H_j$ is the directional regularity of $X_\alpha$ in the direction $u$.

Hence, one can find a direction $u \in S^{d-1}$ in which almost surely $\left( X_\alpha^*(tu) \right)_{t \in \mathbb{R}}$ does not satisfy (33) on $[0, 1]$ for any $s > H_p$. Therefore, almost surely $\left( X_\alpha^*(x) \right)_{x \in \mathbb{R}^d}$ cannot satisfy (33) for any $s > H_p$. Then, by Corollary 5.5, $X_\alpha$ admits $H_p$ as Hölder critical exponent. □

**Remark 5.3.** In the diagonalizable case (see Example 2.2), the $W_j, j = 1 \ldots p$, are the eigenspaces associated with the eigenvalues of $E$. In particular, for $\theta_j$ an eigenvector related to the eigenvalue $\lambda_j = a_j$, the critical Hölder exponent in direction $\theta_j$ is $H_j = 1/a_j$.

**Proposition 5.6.** compared to Theorem 5.4 of [1], shows that operator scaling stable fields, defined through a harmonizable representation share the same sample path properties as the Gaussian ones. Therefore it is natural that the box and the Hausdorff dimensions of their graphs on a compact set are the same as the Gaussian ones, obtained in Theorem 5.6 of [1]. We also refer to Falconer [30] for the definitions and properties of box and the Hausdorff dimension. We denote by $\dim_H A$, respectively $\dim_B A$, the Hausdorff dimension and the box dimension of the set $A$, respectively.

**Proposition 5.7.** Let $\alpha \in (0, 2)$ and $X_\alpha^*$ be as in Theorem 5.1. For $a, b \in \mathbb{R}^d$ with $a_i < b_i$ ($i = 1, \ldots, d$), let $K = \prod_{i=1}^d [a_i, b_i]$ and
\[ G(X_\alpha^*) (\omega) = \{ (x, X_\alpha^*(x)(\omega)) ; x \in K \} \]
be the graph of a realization of the field $X_\alpha^*$ over the compact $K$. Then, almost surely,
\[ \dim_H G(X_\alpha^*) = \dim_B G(X_\alpha^*) = d + 1 - H_p. \]

**Proof.** The proof is very similar to those of Theorem 5.6 [1]. It also uses the same kinds of arguments as in [31]. For sake of completeness we recall the main ideas. Corollary 5.5 allows as usual to state the upper bound
\[ \dim_H G(X_\alpha^*) \leq \overline{\dim_B G(X_\alpha^*)} \leq d + 1 - H_p, \quad \text{almost surely} \]
where $\overline{\dim_B}$ denotes the upper box dimension. The lower bound will also follow from the Frostman criterion (Theorem 4.13(a) in [30]). One has to prove that the integral
is finite to get that almost surely \( \dim_{\mathcal{H}} \mathcal{G}(X^*_\alpha) \geq s \). In our case, the fundamental lemma of [32] allows us to write this integral using the characteristic function of the \( \alpha \)S field \( X^*_\alpha \). Actually, when one remarks that, using Fourier-inversion, \( (\xi^2 + 1)^{-s/2} = \frac{1}{2\pi} \int_{\mathbb{R}} e^{i\xi t} f_\alpha(t) dt \), where \( f_\alpha \in L^\infty(\mathbb{R}) \cap L^1(\mathbb{R}), \) one gets

\[
I_s = \int_{K \times K} \mathbb{E} \left[ \left( (X^*_\alpha(x) - X^*_\alpha(y))^2 + \|x - y\|^\alpha \right)^{-s/2} \right] dx dy,
\]

By a change of variables, as \( f_\alpha \in L^\infty(\mathbb{R}), \) one can find a finite positive constant \( C > 0 \) such that

\[
I_s \leq C \int_{K \times K} \|x - y\|^{-s} \|X^*_\alpha(x) - X^*_\alpha(y)\|^{-1} dx dy
\]
\[
\leq C m_{\alpha}^{-1} \int_{K \times K} \|x - y\|^{-1-s} \tau_E(x-y)^{-1} dx dy,
\]

where \( m_{\alpha} = \min_{\theta \in S_E} \left( d_\alpha \int_{\mathbb{R}^d} |e^{i(\theta, \xi)} - 1|^\alpha \psi(t)^{-\alpha-q} d\xi \right)^{1/\alpha} \). Since \( \int_{K \times K} \|x - y\|^{-1-s} \tau_E(x-y)^{-1} dx dy < +\infty \) as long as \( s < d + 1 - H_p \) (see [1]),

\[
\dim_{\mathcal{H}} \mathcal{G}(X^*_\alpha) \geq \dim_{\mathcal{B}} \mathcal{G}(X^*_\alpha) \geq d + 1 - H_p \quad \text{almost surely},
\]

where \( \dim_{\mathcal{B}} \) denotes the lower box dimension. The proof is then complete. \( \square \)

6. Moving average representation

We proved in the previous section that harmonizable operator scaling stable random fields share many properties with Gaussian operator random fields. In particular, they have locally Hölder sample paths and critical directional Hölder exponent depending on the directions. In the Gaussian case \( \alpha = 2 \), [1] establishes such properties in the framework of both harmonizable and moving average Gaussian operator scaling random fields. However, for stable laws, harmonizable and moving average representations do not have the same behavior as we see in this section.

Let us recall the definition of moving average operator scaling stable random fields introduced in [1]. Let \( 0 < \alpha \leq 2 \). We consider \( M_{\alpha}(dy) \) an independently scattered \( \alpha \)S random measure on \( \mathbb{R}^d \) with Lebesgue control measure, see [4] for details on such random measures. As before, \( q = \text{trace}(E) \). Let \( \varphi : \mathbb{R}^d \to [0, \infty) \) be a continuous \( E \)-homogeneous function. We assume moreover that there exists \( s > 1 \) such that \( \varphi \) is \( (s, E) \)-admissible. According to Definition 2.7 of [1] it means that \( \varphi(x) \neq 0 \) for \( x \neq 0 \) and that for any \( 0 < A < B \) there exists a finite positive constant \( C > 0 \) such that for \( A \leq \|y\| \leq B \),

\[
|\varphi(x + y) - \varphi(y)| \leq C \tau_E(x)^s
\]

holds for any \( \tau_E(x) \leq 1 \).

**Definition 6.1.** The random field

\[
Z_\alpha(x) = \int_{\mathbb{R}^d} \left( \varphi(x - y)^{1-q/\alpha} - \varphi(-y)^{1-q/\alpha} \right) M_{\alpha}(dy), \quad x \in \mathbb{R}^d
\]

is called moving average operator scaling stable random field.
Remark 6.1. As in the harmonizable case, the representation we use is not exactly the same one as in [1]. However, as in Remark 2.1, up to change the parametrization, the class defined by (34) and the class of moving average random fields defined in [1] are the same.

From Theorem 3.1 and Corollary 3.2 of [1], since \( \varphi \) is \((s, E)\)-admissible with \( s > 1 \), the random field \( Z_\alpha \) is well-defined, stochastically continuous, has stationary increments and satisfies the following operator scaling property

\[
\forall c > 0, \quad \left\{ Z_\alpha(c E x); x \in \mathbb{R}^d \right\} \overset{(fdd)}{=} \left\{ c Z_\alpha(x); x \in \mathbb{R}^d \right\},
\]

as the harmonizable field \( X_\alpha \).

In the Gaussian case (\( \alpha = 2 \)), the variograms of \( Z_2 \) and \( X_2 \), respectively defined by (34) and (3), are similar. Then, [1] proves that \( Z_2 \) and \( X_2 \) admit the same critical global and directional Hölder exponents. Moreover, \( Z_2 \) satisfies (32) for \( \beta = 0 \) and then the conclusions of Proposition 5.3 and Corollary 5.4 hold for \( \beta = 0 \). However, when \( \alpha \in (0, 2) \), let us recall that moving average self-similar \( \alpha \)-stable random motions does not have in general continuous sample paths (see [4]). The next proposition states the same property for \( Z_\alpha \).

**Proposition 6.1.** Let \( \alpha \in (0, 2) \) and \( Z_\alpha \) be defined by (34). Assume \( d \geq 2 \). Then, any modification of the random field \( Z_\alpha \) is almost surely unbounded on every open ball.

**Proof.** Let us remark that \( \varphi(0) = 0 \) by continuity and \( E \)-homogeneity and \( q = \sum_{j=1}^{d} \alpha_j > d > \alpha \) since \( d \geq 2 \). Then, for any open ball \( U \), since \( U^* = U \cap \mathbb{Q}^d \) is a dense sequence in \( U \), for any \( y \in U \)

\[
 f^*(U^*, y) := \sup_{x \in U^*} \left| \varphi(x - y)^{1-q/\alpha} - \varphi(-y)^{1-q/\alpha} \right| = +\infty.
\]

Then \( \int_{\mathbb{R}^d} f^*(U^*, y)^\alpha \, dy = +\infty \) and the necessary condition for sample boundedness (10.2.14) of Theorem 0.2.3 p. 450 of [4] fails. Theorem 10.2.3 and Corollary 9.5.5 of [4] give the conclusion. \( \square \)

**Acknowledgments**

The authors are very grateful to Yimin Xiao and the anonymous referee for their careful reading and their relevant remarks contributing to the improvement of the manuscript.

**Appendix**

**Proof of Lemma 3.2.** The lower bound is straightforward. Actually, for any \( t > 0 \), \( t^\lambda \) is an eigenvalue of the matrix \( t^J \) and therefore \( t^\lambda = \| t^\lambda \| \leq \| t^J \| \).

Let us prove the upper bound. Let us recall that the norm defined for a matrix \( A = (a_{ij})_{1 \leq i, j \leq d'} \) by \( \| A \|_\infty = \max_{1 \leq i \leq d'} \sum_{j=1}^{d'} |a_{ij}| \) is the subordinated norm of the infinite norm \( \| x \|_\infty = \max_{1 \leq i \leq d'} |x_i| \) for \( x \in \mathbb{R}^{d'} \).

Let us first assume that \( J \) is a Jordan cell matrix of size \( l \). In this case \( \lambda = a \in \mathbb{R} \) and

\[
 t^J = t^a = \begin{pmatrix} 1 & 0 & \cdots & 0 \\ \log t & 1 & 0 & \vdots \\ \vdots & \ddots & \ddots & 0 \\ (\log t)^{l-1} & \cdots & \log t & 1 \end{pmatrix}. 
\]

From the definition of the subordinated norm $\| \cdot \|_\infty$, we can deduce that $\| r^J \|_\infty = t^a \sum_{j=0}^{l-1} \frac{\log t^j}{j!}$. Then, for any $t \in (0, e^{-1}] \cup [e, +\infty)$ we get $|\log t| \geq 1$ and

$$
\| r^J \| \leq \sqrt{t} \| r^J \|_\infty \leq \sqrt{t} t^a |\log t|^{l-1} \sum_{j=0}^{l-1} \frac{1}{j!}.
$$

Therefore, for any $t \in (0, e^{-1}] \cup [e, +\infty)$,

$$
\| r^J \| \leq \sqrt{t} t^a |\log t|^{l-1}.
$$

Let us now assume that $J$ is a block of the form (11) of size $2l$ associated with the eigenvalue $\lambda = a + ib$ for $b \neq 0$. Then $r^J = t^a R(t) N(t)$ where

$$
R(t) = \begin{pmatrix}
R_b(t) & 0 & \ldots & 0 \\
0 & R_b(t) & 0 & \vdots \\
\vdots & \ddots & \ddots & 0 \\
0 & \ldots & 0 & R_b(t)
\end{pmatrix}
$$

with $R_b(t) = \begin{pmatrix}
\cos(b \log t) & -\sin(b \log t) \\
\sin(b \log t) & \cos(b \log t)
\end{pmatrix}$,

and

$$
N(t) = \begin{pmatrix}
I_2 & 0 & \ldots & 0 \\
N_1(t) & I_2 & 0 & \vdots \\
\vdots & \ddots & \ddots & 0 \\
N_{l-1}(t) & \ldots & N_1(t) & I_2
\end{pmatrix}
$$

with $N_j(t) = \begin{pmatrix}
|\log t|^j & 0 \\
0 & \frac{|\log t|^j}{j!}
\end{pmatrix}$.

Hence,

$$
\| r^J \| \leq t^a \| R(t) \| \| N(t) \|.
$$

Since $R(t)$ is an orthogonal matrix, $\| R(t) \| = 1$. Furthermore, $N(t)$ is a $(2l) \times (2l)$ matrix and

$$
\| N(t) \| \leq \sqrt{2l} \| N(t) \|_\infty = \sqrt{2l} \sum_{j=0}^{l-1} \frac{|\log t|^j}{j!}.
$$

Therefore, we also obtain that

$$
\| r^J \| \leq \sqrt{2l} t^a |\log t|^{l-1}
$$

for any $t \in (0, e^{-1}] \cup [e, +\infty)$. \(\square\)

**Proof of Proposition 3.3.** Let $r \in (0, 1)$ and $x \in \bigoplus_{k=j_0}^{j} W_k \setminus \{0\}$ such that $\|x\| \leq r$.

We first establish the lower bound of Proposition 3.3. Since for any $r_0 \in (0, r)$ the function

$$
y \mapsto \|y\|^{H_0} |\log \|y\||^{-H_0} (p_{j_0, j-1})^{H_0} \tau_E(y)^{-1}
$$

is continuous on the compact set $\{ y \in \mathbb{R}^d / r_0 \leq \|y\| \leq r \}$, the key issue here is to prove the lower bound around the origin. Moreover, let us remark that one can find $r_0 \in (0, r)$ such that for any $y \in \mathbb{R}^d$ with $\|y\| \leq r_0$, we have $\tau_E(y) \leq e^{-1}$. Then, without loss of generality, we can assume that $\|x\| \leq r_0$. Hence, $x = \tau_E(x)E \ell_E(x)$ with $\tau_E(x) \leq e^{-1}$. Since $\mathbb{R}^d = \bigoplus_{k=1}^{P} W_k$, ...
\( \ell_E(x) = \sum_{k=1}^p \ell_k(x) \) with \( \ell_k(x) \in W_k, k = 1, \ldots, p \). For any \( k = 1, \ldots, p \), let \( L_k \) be the coordinates of \( \ell_k(x) \) in the basis \( \left( f_{\sum_{i=1}^{k-1} l_i+1}, \ldots, f_{\sum_{i=1}^{k} l_i} \right) \) of \( W_k \). Hence, by definition of \( P \),

\[
P^{-1} \ell_E(x) = \begin{pmatrix} L_1 \\ \vdots \\ L_p \end{pmatrix} \quad \text{and} \quad x = \tau_E(x)^E \ell_E(x) = P \begin{pmatrix} \tau_E(x)^{J_1} L_1 \\ \vdots \\ \tau_E(x)^{J_p} L_p \end{pmatrix}.
\]

Since \( x \in \bigoplus_{k=j_0}^i W_k \), \( \ell_E(x) \in \bigoplus_{k=j_0}^i W_k \) and then \( L_k = 0 \) for \( k \not\in \{j_0, \ldots, j\} \). Then,

\[
\|x\| \leq \|P\| \left( \sum_{k=j_0}^j \|\tau_E(x)^{J_k} L_k\|^2 \right)^{1/2} \leq \|P\| \left( \sum_{k=j_0}^j \|\tau_E(x)^{J_k}\|^2 \|L_k\|^2 \right)^{1/2}.
\]

By Lemma 3.2, since \( \tau_E(x) \leq e^{-1} \),

\[
\|x\| \leq \sqrt{2} e \|P\| \left( \sum_{k=j_0}^j l_k \tau_E(x)^{2a_k} |\log \tau_E(x)|^{2(l_k-1)} \|L_k\|^2 \right)^{1/2}.
\]

Since \( \tau_E(x) \leq e^{-1} \), \( a_k \geq a_{j_0} \) and \( l_k \leq p_{j_0,j} = \max_{j_0 \leq i \leq j} l_i \leq d \),

\[
\|x\| \leq \sqrt{2d} e \|P\| \|\tau_E(x)^{a_{j_0}} [\log \tau_E(x)]^{(p_{j_0,j}-1)} \sum_{k=j_0}^j \|L_k\|^2 \right)^{1/2} \leq \sqrt{2d} e \|P\| \|\tau_E(x)^{a_{j_0}} [\log \tau_E(x)]^{(p_{j_0,j}-1)} \|P^{-1}\| \ell_E(x) \|.
\]

Then,

\[
\|x\| \leq \sqrt{2d} M_E \|P\| \|P^{-1}\| \tau_E(x)^{a_{j_0}} [\log \tau_E(x)]^{(p_{j_0,j}-1)}, \tag{35}
\]

where \( M_E \) is defined by (10).

Consider the logarithm of both sides of Eq. (35). Then, since \( a_{j_0} > 0 \), one can find two finite positive constants \( c_1 \) and \( c_2 \) such that for \( \tau_E(x) \) small enough,

\[
\log \|x\| \leq c_1 \log \tau_E(x) + c_2.
\]

Hence, choosing \( r_0 \) small enough, one can find a finite constant \( C > 0 \) such that

\[
|\log \tau_E(x)| \leq C |\log \|x\||. \tag{36}
\]

Using (36) in (35), we obtain that there exists a finite constant \( C > 0 \) such that for \( \|x\| \leq r_0 \)

\[
\|x\|^{-H_{j_0}} [\log \|x\|]^{-H_{j_0}(p_{j_0,j}-1)} \leq C \ell_E(x),
\]

which gives the lower bound of Proposition 3.3, up to change \( C \).

Let us now establish the upper bound of Proposition 3.3. Since for any \( r_0 \in (0, r) \) the function

\[
y \mapsto \frac{\tau_E(y)}{\|y\|^{H_j} [\log \|y\|]^{H_j(p_{j_0,j}-1)}}
\]
is continuous on the compact set \( \{ y \in \mathbb{R}^d / r_0 \leq \| y \| \leq r \} \), the key issue here is also to prove the upper bound around the origin. Therefore, we can also assume that \( \| x \| \leq r_0 \), with \( r_0 \) chosen as previously, such that \( \tau_E(x) \leq e^{-1} \).

Let us write \( x = \sum_{k=1}^p x_k \) with each \( x_k \in W_k \). We then denote by \( X_k \) the coordinates of \( x_k \) in the basis \( \left( f_{\sum_{k'=1}^{k-1} \ell_k}^{i_k + 1}, \ldots, f_{\sum_{k'=1}^{k-1} \ell_k}^{i_k} \right) \) of \( W_k \). Since \( x \in \bigoplus_{k=j_0}^j W_k \), \( X_k = 0 \) for every \( k \not\in \{j_0, \ldots, j\} \). Hence, by definition of \( \bar{P} \),

\[
P^{-1}x = \begin{pmatrix} X_1 \\ \vdots \\ X_p \end{pmatrix} \quad \text{and} \quad \ell_E(x) = \tau_E(x)^{-1} = P \begin{pmatrix} \tau_E(x)^{-1} X_1 \\ \vdots \\ \tau_E(x)^{-1} X_p \end{pmatrix}.
\]

Then, \( \| \ell_E(x) \| \leq \| P \| \left( \sum_{k=j_0}^j \| \tau_E(x)^{-1} X_k \| \right)^{1/2} \) and, since \( \tau_E(x)^{-1} \geq e \), Lemma 3.2 yields that

\[
\| \ell_E(x) \| \leq \sqrt{2e} \| P \| \left( \sum_{j=j_0}^j l_k \tau_E(x)^{-2a_k} \| \log \tau_E(x) \|^2 \| X_k \|^2 \right)^{1/2}.
\]

Hence, using the facts that \( \tau_E(x)^{-1} \geq e > 1 \), \( a_k \leq a_j \) and \( l_k \leq p_{j_0, j} \),

\[
0 < m_E = \min_{S_E} \| y \| \leq \sqrt{2de} \| P \| \left( \sum_{j=j_0}^j \| \tau_E(x)^{-a_j} \| \| \log \tau_E(x) \|^2 \| X_k \|^2 \right)^{1/2} \leq \sqrt{2de} \| P \| \left( \sum_{j=j_0}^j \| \tau_E(x)^{-a_j} \| \| \log \tau_E(x) \|^2 \| X_k \|^2 \right)^{1/2}.
\]

Then, by (36) and since \( \| P^{-1}x \| \leq \| P^{-1} \| \| x \| \), there exists a finite constant \( C > 0 \) such that for \( \| x \| \leq r_0 \),

\[
\tau_E(x) < C \| x \|^{H_j} \| \log \| x \| \|^{H_j} (p_{j_0, j}^{-1}),
\]

which, up to change \( C \), gives the upper bound of Proposition 3.3 and concludes the proof. \( \square \)

**Proof of Lemma 5.2.** It is sufficient to consider

\[
I(h) = \mathbb{E} \left( m(\xi_n)^{1-2/\alpha} \min \left( M_E \left\| hE^\ell \xi_n \right\| , 2 \right)^2 \psi(\xi_n)^{2-2q/\alpha} \right)
\]

with \( M_E \) defined by (10) and where the density distribution \( m \) of \( \xi_n \) is associated with \( \eta > 0 \) by (17). By definition,

\[
I(h) = \int_{\mathbb{R}^d} m(\xi)^{1-2/\alpha} \psi(\xi)^{2-2q/\alpha} \min \left( M_E \left\| hE^\ell \xi \right\| , 2 \right)^2 d\xi.
\]

Using the formula of integration in *polar coordinates* with respect to \( E^\ell \), see Proposition 3.1,

\[
I(h) = \int_{S_{E^\ell}} \int_0^{+\infty} m(r^{E^\ell} \theta)^{1-2/\alpha} \psi(r^{E^\ell} \theta)^{2-2q/\alpha} \times \min \left( M_E \left\| (hr)^E \theta \right\| , 2 \right)^2 r^{d-1} dr \sigma_{E^\ell}(d\theta).
\]
Since $\psi$ is $E'$-homogeneous,

$$I(h) = \int_{S_{E'}} \int_0^{+\infty} m \left( r_{E'} h \right)^{1-2/\alpha} \psi(\theta)^{-2-2q/\alpha} \times \min \left( M_E \left\| (hr)_{E'} \right\| , 2 \right)^2 r^{-2+q-2q/\alpha} d\sigma_{E'}(d\theta)$$

$$= c_\eta^{1-2/\alpha} \int_{S_{E'}} \int_0^{+\infty} \psi(\theta)^{-2-2q/\alpha} \times \min \left( M_E \left\| (hr)_{E'} \right\| , 2 \right)^2 r^{-3} \left| \log(r) \right|^{(1+\eta)/(2/\alpha-1)} d\sigma_{E'}(d\theta).$$

By the change of variable $\rho = hr$, $I(h)$ is equal to

$$c_\eta^{1-2/\alpha} h^2 \int_{S_{E'}} \int_0^{+\infty} \psi(\theta)^{-2-2q/\alpha}$$

$$\times \min \left( M_E \left\| \rho_{E'} \right\| , 2 \right)^2 \rho^{-3} \left| \log \left( \frac{\rho}{h} \right) \right|^{(1+\eta)/(2/\alpha-1)} d\sigma_{E'}(d\theta).$$

For any $\gamma \in (0, 1)$, there exists $A_\gamma$ such that for every $\rho > 0$ and every $h \leq 1 - \gamma$,

$$\left| \log \left( \frac{\rho}{h} \right) \right| = \left| \log(\rho) - \log(h) \right| \leq A_\gamma \left| \log(\rho) \right| + 1 \left| \log(h) \right|.$$ 

Since $2/\alpha > 1$,

$$I(h) \leq A_\gamma^{2/\alpha-1} c_\eta^{1-2/\alpha} h^2 \left| \log(h) \right|^{(1+\eta)/(2/\alpha-1)} (I_1 + I_2)$$

with

$$I_1 = 4 \int_{S_{E'}} \psi(\theta)^{-2-2q/\alpha} d\sigma_{E'}(d\theta) \int_1^{+\infty} \rho^{-3} \left| \log(\rho) \right| + 1 \left| \log(h) \right|^{(1+\eta)/(2/\alpha-1)} d\rho$$

and

$$I_2 = M_E^2 M_{E'}^2 \int_{S_{E'}} \psi(\theta)^{-2-2q/\alpha} d\sigma_{E'}(d\theta) \int_0^1 \left\| \rho_{E'} \right\|^2 \rho^{-3} \left| \log(\rho) \right| + 1 \left| \log(\rho) \right|^{(1+\eta)/(2/\alpha-1)} d\rho,$$
